Abstract

We study time dependence of exchange symmetry properties of Bell states when two qubits interact with local baths having identical parameters. In case of classical noise, we consider a decoherence Hamiltonian which is invariant under swapping the first and second qubits. We find that as the system evolves in time, two of the three symmetric Bell states preserve their qubit exchange symmetry with unit probability, whereas the symmetry of the remaining state survives with a maximum probability of 0.5 at the asymptotic limit. Next, we examine the exchange symmetry properties of the same states under local, quantum mechanical noise which is modeled by two identical spin baths. Results turn out to be very similar to the classical case. We identify decoherence as the main mechanism leading to breaking of qubit exchange symmetry.

I. INTRODUCTION

Since the early days of quantum mechanics, it has been known that certain quantum states have a mysterious non-local behavior [1]. The phenomenon responsible for these non-local correlations among the subsystems of a composite quantum system is called entanglement [2]. Quantum entanglement, having no classical counterpart, is believed to be one of the characteristic features of quantum mechanics. Besides its foundational importance for the quantum theory, entanglement is also considered as the resource of quantum computation, quantum cryptography and quantum information processing [3]. In recent years, it has been extensively studied with various motivations [4]. However, entanglement of quantum systems, as all other quantum traits, is very fragile when they are exposed to external disturbances, which is inevitably the case in real world situations.

Decoherence, the process through which quantum states lose their phase relations irreversibly due to interactions with the environment, is crucial for understanding the emergence of classical behavior in quantum systems [5]. It also presents a major challenge for the realization of quantum information processing protocols since protection of non-local correlations against undesirable external disturbances is essential for the reliability of such protocols. Consequently, understanding the decoherence effect of the environment on entangled systems is an important issue. This problem has been currently addressed in literature, considering both local and collective interactions of qubits and qutrits with the environment. While some authors examined the effects of classical stochastic noise fields [6-9], others studied the same problem for large spin environments [10-15].

In this work, we focus on a different aspect of a decoherence process of entangled states. Certain two-qubit entangled states have the property that they remain unchanged under the exchange of two qubits. We will concentrate on a decoherence model which also has an exchange symmetry, i.e., having a Hamiltonian invariant upon swapping the first and second qubits. Our goal is to understand how the exchange symmetry properties of symmetric pure states alter as the quantum system evolves in time for a symmetric Hamiltonian which embodies the effect of local and identical noise fields on qubits. More specifically, we will investigate the exchange symmetry properties of three of the four Bell states. Bell states

are defined as maximally entangled quantum states of two-qubit systems and given as

$$|B_1\rangle = \frac{1}{\sqrt{2}}(|00\rangle + |11\rangle), \quad (1)$$

$$|B_2\rangle = \frac{1}{\sqrt{2}}(|00\rangle - |11\rangle), \quad (2)$$

$$|B_3\rangle = \frac{1}{\sqrt{2}}(|01\rangle + |10\rangle), \quad (3)$$

$$|B_4\rangle = \frac{1}{\sqrt{2}}(|01\rangle - |10\rangle). \quad (4)$$

We will only consider the first three of these states which are symmetric under exchange operation. However, our discussion can be extended to include anti-symmetric states like $|B_4\rangle$. The first three Bell states are among the symmetric pure two-qubit states which can be represented in the most general case by the density matrix

$$\rho_{sym} = \begin{pmatrix} |a|^2 & ac^* & ac^* & ab^* \\ ca^* & |c|^2 & |c|^2 & cb^* \\ ca^* & |c|^2 & |c|^2 & cb^* \\ ba^* & bc^* & bc^* & |b|^2 \end{pmatrix}, \quad (5)$$

where $|a|^2 + 2|c|^2 + |b|^2 = 1$. After classical noise calculations, we will briefly discuss the exchange symmetry properties of the same states for local and quantum mechanical noise which is modeled via two identical large spin environments.

II. LOCAL CLASSICAL NOISE

We assume that the two qubits are interacting with separate baths locally and the initial two-qubit system is not entangled with the local baths. The model Hamiltonian we consider was first introduced and studied by Yu and Eberly [6] and can be thought as the representative of the class of interactions which generate a pure dephasing process that is defined as

$$H(t) = -\frac{1}{2}\mu[n_A(t)(\sigma_z \otimes I) + n_B(t)(I \otimes \sigma_z)], \quad (6)$$

where we take $\hbar = 1$ and σ_z is the Pauli matrix

$$\sigma_z = \begin{pmatrix} 1 & 0 \\ 0 & -1 \end{pmatrix}. \quad (7)$$

Here μ is the gyromagnetic ratio and $n_A(t), n_B(t)$ are stochastic noise fields that lead to statistically independent Markov processes satisfying

$$\langle n_i(t) \rangle = 0, \quad (8)$$

$$\langle n_i(t) n_i(t') \rangle = \frac{\Gamma_i}{\mu^2} \delta(t - t'), \quad (9)$$

where $\langle \dots \rangle$ stands for ensemble average and Γ_i (i=A,B) are the damping rates associated with the stochastic fields $n_A(t)$ and $n_B(t)$.

The time evolution of the system's density matrix can be obtained as

$$\rho(t) = \langle U(t) \rho(0) U^\dagger(t) \rangle, \quad (10)$$

where ensemble averages are evaluated over the two noise fields $n_A(t)$ and $n_B(t)$ and the time evolution operator, $U(t)$, is given by

$$U(t) = \exp[-i \int_0^t dt' H(t')]. \quad (11)$$

The resulting density matrix in the product basis $\{|00\rangle, |01\rangle, |10\rangle, |11\rangle\}$ can be written as

$$\rho(t) = \begin{pmatrix} \rho_{11} & \rho_{12}\gamma_B & \rho_{13}\gamma_A & \rho_{14}\gamma_A\gamma_B \\ \rho_{21}\gamma_B & \rho_{22} & \rho_{23}\gamma_A\gamma_B & \rho_{24}\gamma_A \\ \rho_{31}\gamma_A & \rho_{32}\gamma_A\gamma_B & \rho_{33} & \rho_{34}\gamma_B \\ \rho_{41}\gamma_A\gamma_B & \rho_{42}\gamma_A & \rho_{43}\gamma_B & \rho_{44} \end{pmatrix}, \quad (12)$$

where ρ_{ij} stands for the elements of the initial density matrix, $\rho(0)$, and γ_A, γ_B are given by

$$\gamma_A(t) = e^{-t\Gamma_A/2}, \quad \gamma_B(t) = e^{-t\Gamma_B/2}. \quad (13)$$

For our purposes, we want our two local baths to be identical in a sense that they have the same dephasing rate Γ . Therefore, we let $\Gamma_A = \Gamma_B = \Gamma$. The resulting density matrix of the system with the consideration of identical baths is now given by

$$\rho(t) = \begin{pmatrix} \rho_{11} & \rho_{12}\gamma & \rho_{13}\gamma & \rho_{14}\gamma^2 \\ \rho_{21}\gamma & \rho_{22} & \rho_{23}\gamma^2 & \rho_{24}\gamma \\ \rho_{31}\gamma & \rho_{32}\gamma^2 & \rho_{33} & \rho_{34}\gamma \\ \rho_{41}\gamma^2 & \rho_{42}\gamma & \rho_{43}\gamma & \rho_{44} \end{pmatrix}, \quad (14)$$

where $\gamma_A = \gamma_B = \gamma$.

III. OPERATOR-SUM REPRESENTATION OF DECOHERENCE

To examine the symmetry properties, we need to express the dynamical evolution of $\rho(t)$ in terms of quantum operations. The decoherence process of our quantum system can be regarded as a completely positive linear map $\Phi(\rho)$, that takes an initial state $\rho(0)$ and maps it to some final state $\rho(t)$ [3]. For every completely positive linear map there exists an operator-sum representation which is known as Kraus representation [16-18]. The effect of the map is given by

$$\rho(t) = \Phi(\rho(0)) = \sum_{\mu=1}^N K_{\mu}(t)\rho(0)K_{\mu}^{\dagger}(t), \quad (15)$$

where K_{μ} are the Kraus operators which satisfy the unit trace condition

$$\sum_{\mu=1}^N K_{\mu}^{\dagger}(t)K_{\mu}(t) = I. \quad (16)$$

The Kraus operator approach provides an elegant way to study the decoherence process. In order to describe the internal decoherence dynamics of the system, all we need to know is the Kraus operator set which inherently contains the entire information about environment. The operator-sum representation of our completely positive linear map, $\Phi(\rho)$, which reflects the effect of the stochastic process, can be obtained by studying the mapping called Choi-Jamiolkowski isomorphism [17-18]. In our investigation, it turns out that the effect of the mapping, $\Phi(\rho)$, on the two-qubit system can be expressed by a set of four Kraus operators as

$$K_1 = \frac{1}{\sqrt{2}} \begin{pmatrix} -\omega(t) & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & \omega(t) \end{pmatrix}, \quad (17)$$

$$K_2 = \frac{1}{\sqrt{2}} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & -\omega(t) & 0 & 0 \\ 0 & 0 & \omega(t) & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (18)$$

$$K_3 = \frac{1}{2} \begin{pmatrix} \alpha(t) & 0 & 0 & 0 \\ 0 & -\alpha(t) & 0 & 0 \\ 0 & 0 & -\alpha(t) & 0 \\ 0 & 0 & 0 & \alpha(t) \end{pmatrix}, \quad (19)$$

$$K_4 = \frac{1}{2} \begin{pmatrix} \beta(t) & 0 & 0 & 0 \\ 0 & \beta(t) & 0 & 0 \\ 0 & 0 & \beta(t) & 0 \\ 0 & 0 & 0 & \beta(t) \end{pmatrix}, \quad (20)$$

where $\omega(t)$, $\alpha(t)$ and $\beta(t)$ are given by

$$\omega(t) = \sqrt{1 - \gamma(t)^2}, \quad \alpha(t) = \gamma(t) - 1, \quad \beta(t) = \gamma(t) + 1. \quad (21)$$

Since different environmental interactions may result in the same dynamics on the system, the operator-sum representation of a quantum process is not unique. The collective action of our set of the four Kraus operators $\{K_1, K_2, K_3, K_4\}$ on the density matrix of the two-qubit quantum system are equivalent to the collective action of another set of Kraus operators $\{E_1, E_2, E_3, E_4\}$ if and only if there exists complex numbers u_{ij} such that $E_i = \sum_j u_{ij} K_j$ where u_{ij} are the elements of a 4×4 unitary matrix [3]. The unitary freedom will provide us an easy way to introduce exchange symmetry condition.

IV. EXCHANGE SYMMETRY OF BELL STATES UNDER DECOHERENCE

In order to analyze the exchange symmetries of symmetric Bell states $|B_1\rangle, |B_2\rangle$ and $|B_3\rangle$, we exploit the unitary freedom on the operator-sum representation. Consider the most general 4×4 unitary matrix with complex elements

$$U = \begin{pmatrix} u_{11} & u_{12} & u_{13} & u_{14} \\ u_{21} & u_{22} & u_{23} & u_{24} \\ u_{31} & u_{32} & u_{33} & u_{34} \\ u_{41} & u_{42} & u_{43} & u_{44} \end{pmatrix}, \quad (22)$$

where $U^\dagger U = I$.

The mapping described by the Kraus operators $\{K_1, K_2, K_3, K_4\}$, via unitary freedom, is equivalent to the mappings described by the following four Kraus operators

$$E_\mu = \text{Diag}\left[-\frac{\omega u_{\mu 1}}{\sqrt{2}} + \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}, -\frac{\omega u_{\mu 2}}{\sqrt{2}} - \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}, \frac{\omega u_{\mu 2}}{\sqrt{2}} - \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}, \frac{\omega u_{\mu 1}}{\sqrt{2}} + \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}\right], \quad (23)$$

where $\mu = 1, 2, 3, 4$.

A. Exchange Symmetries of $|B_1\rangle$ and $|B_2\rangle$

Having calculated all possible Kraus operator sets, we are in a position to evaluate the possible final states when the initial state is $|B_1\rangle$ or $|B_2\rangle$. The density matrices of possible final states are obtained as

$$\rho_\mu^{B_1}(t) = \frac{E_\mu(t)\rho^{B_1}(0)E_\mu^\dagger(t)}{\text{Tr}(E_\mu(t)\rho^{B_1}(0)E_\mu^\dagger(t))}, \quad \rho_\mu^{B_2}(t) = \frac{E_\mu(t)\rho^{B_2}(0)E_\mu^\dagger(t)}{\text{Tr}(E_\mu(t)\rho^{B_2}(0)E_\mu^\dagger(t))}, \quad (24)$$

where $\mu = 1, 2, 3, 4$ and $\rho^{B_i}(0) = |B_i\rangle\langle B_i|$ for $i = 1, 2$. The explicit forms of the density matrices $\rho_\mu^{B_1}(t)$ and $\rho_\mu^{B_2}(t)$ are given by

$$\rho_\mu^{B_1}(t) = \frac{1}{|e|^2 + |f|^2} \begin{pmatrix} |e|^2 & 0 & 0 & ef^* \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ e^*f & 0 & 0 & |f|^2 \end{pmatrix}, \quad (25)$$

$$\rho_\mu^{B_2}(t) = \frac{1}{|e|^2 + |f|^2} \begin{pmatrix} |e|^2 & 0 & 0 & -ef^* \\ 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 \\ -e^*f & 0 & 0 & |f|^2 \end{pmatrix}, \quad (26)$$

where

$$e = \left(\frac{-\omega u_{\mu 1}}{\sqrt{2}} + \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}\right), \quad f = \left(\frac{\omega u_{\mu 1}}{\sqrt{2}} + \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}\right). \quad (27)$$

Obviously, the symmetry condition given in Eq. (5) brings no restriction on these density matrices. Thus, it is guaranteed that the Bell states $|B_1\rangle$ and $|B_2\rangle$ always preserve their exchange symmetry as they evolve in time under our model Hamiltonian.

B. Exchange Symmetry of $|B_3\rangle$

The density matrices of the possible final states for $|B_3\rangle$ are written as

$$\rho_\mu^{B_3}(t) = \frac{E_\mu(t)\rho^{B_3}(0)E_\mu^\dagger(t)}{\text{Tr}(E_\mu(t)\rho^{B_3}(0)E_\mu^\dagger(t))}, \quad (28)$$

where $\mu = 1, 2, 3, 4$ and $\rho^{B_3}(0) = |B_3\rangle\langle B_3|$. The explicit form of the density matrix $\rho_\mu^{B_3}(t)$ is

$$\rho_\mu^{B_3}(t) = \frac{1}{|r|^2 + |s|^2} \begin{pmatrix} 0 & 0 & 0 & 0 \\ 0 & |r|^2 & rs^* & 0 \\ 0 & r^*s & |s|^2 & 0 \\ 0 & 0 & 0 & 0 \end{pmatrix}, \quad (29)$$

where

$$r = \left(\frac{-\omega u_{\mu 2}}{\sqrt{2}} - \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}\right), \quad s = \left(\frac{\omega u_{\mu 2}}{\sqrt{2}} - \frac{\alpha u_{\mu 3}}{2} + \frac{\beta u_{\mu 4}}{2}\right). \quad (30)$$

As can be seen from the form of the density matrix of the most general two-qubit symmetric pure state in Eq. (5), for possible final states to be symmetric we need all non-zero elements of the matrix in Eq. (29) to be equal to each other, that is, $r = s$. This condition can only be satisfied in case of $u_{\mu 2} = 0$. We can immediately conclude that it is impossible for all of the possible final states to be symmetric since any 4×4 unitary matrix has to satisfy the condition that $|u_{12}|^2 + |u_{22}|^2 + |u_{32}|^2 + |u_{42}|^2 = 1$. Thus, $|B_3\rangle$ cannot evolve in time under our model Hamiltonian in a way that preserves its qubit exchange symmetry with unit probability. In other words, the exchange symmetry of this two-qubit state has to be broken with some non-zero probability. Considering the symmetry of the initial state and the Hamiltonian this is a very interesting result. A natural question is the maximum probability of finding a symmetric possible final state as the system evolves in time. In order to answer this question, we need to consider three different cases, namely, the cases of having one, two or three symmetric possible final states.

If we assume only one of the possible final states to be symmetric, say the outcome of E_1 ($u_{12} = 0$), then the probability of getting a symmetric output state is given by

$$P_{sym}(t \rightarrow \infty) = \frac{1}{4}|u_{13} + u_{14}|^2. \quad (31)$$

If we assume two of the possible final states to be symmetric, say the outcomes of E_1 and E_2 ($u_{12} = 0, u_{22} = 0$), then the probability of having a symmetric output state is given by

$$P_{sym}(t \rightarrow \infty) = \frac{1}{4}|u_{13} + u_{14}|^2 + \frac{1}{4}|u_{23} + u_{24}|^2. \quad (32)$$

Finally, if three of the possible final states are symmetric, say the outcomes of E_1 , E_2 and E_3 ($u_{12} = 0$, $u_{22} = 0$, $u_{32} = 0$), then the probability of having a symmetric output state is given by

$$P_{sym}(t \rightarrow \infty) = \frac{1}{4}|u_{13} + u_{14}|^2 + \frac{1}{4}|u_{23} + u_{24}|^2 + \frac{1}{4}|u_{33} + u_{34}|^2. \quad (33)$$

In all of these possible cases, the maximum probability of finding a symmetric final state turns out to be 0.5.

V. LOCAL QUANTUM NOISE

When it comes to modeling the baths as large spin environments, one of the simplest decoherence models, introduced in [19], is that of two central spins interacting with N independent spins through the Hamiltonian [13]

$$H = c_{1z} \sum_{k=1}^{N_1} \hbar \omega_{1k} \sigma_{1kz} + c_{2z} \sum_{k=1}^{N_2} \hbar \omega_{2k} \sigma_{2kz}. \quad (34)$$

This model describes two central spins, with z -component operators c_{1z} and c_{2z} , coupled to bath spins represented by σ_{nkz} , where $n = 1, 2$ labels the baths and $k = 1, 2, 3, \dots, N_n$ labels the individual spins. All spins are assumed to be $1/2$ and c_{1z} , c_{2z} and σ_{nkz} denote the corresponding Pauli matrices. If we assume that the central spins are not entangled with the spin baths at $t = 0$, the initial state will be in product form $|\Psi(0)\rangle = |\Psi_c(0)\rangle |\Psi_{\sigma 1}(0)\rangle |\Psi_{\sigma 2}(0)\rangle$ where

$$|\Psi_c(0)\rangle = (a_{\uparrow\uparrow} |\uparrow\uparrow\rangle + a_{\uparrow\downarrow} |\uparrow\downarrow\rangle + a_{\downarrow\uparrow} |\downarrow\uparrow\rangle + a_{\downarrow\downarrow} |\downarrow\downarrow\rangle), \quad (35)$$

with

$$|\Psi_{\sigma n}(0)\rangle = \bigotimes_{k=1}^{N_n} (\alpha_{nk} |\uparrow_{nk}\rangle + \beta_{nk} |\downarrow_{nk}\rangle), \quad (36)$$

where $|\uparrow_{nk}\rangle$ and $|\downarrow_{nk}\rangle$ are eigenstates of σ_{nkz} with eigenvalues $+1$ and -1 , respectively, and $|\alpha_{nk}|^2 + |\beta_{nk}|^2 = 1$.

The reduced density matrix of two central spins at later times will be given by tracing out the bath degrees of freedom from the total density matrix of the system, $\rho(t)$, as $\rho_c(t) = \text{Tr}_\sigma \rho(t)$ where subscript σ means that trace is evaluated by summing over all possible nk

states and $\rho(t) = |\Psi(t)\rangle\langle\Psi(t)|$. The resulting reduced density matrix in product basis $\{|\uparrow\uparrow\rangle, |\uparrow\downarrow\rangle, |\downarrow\uparrow\rangle, |\downarrow\downarrow\rangle\}$ is found to be

$$\rho_c = \begin{pmatrix} |a_{\uparrow\uparrow}|^2 & a_{\uparrow\uparrow}a_{\uparrow\downarrow}^*r_2 & a_{\uparrow\uparrow}a_{\downarrow\uparrow}^*r_1 & a_{\uparrow\uparrow}a_{\downarrow\downarrow}^*r_1r_2 \\ a_{\uparrow\uparrow}^*a_{\uparrow\downarrow}r_2^* & |a_{\uparrow\downarrow}|^2 & a_{\uparrow\downarrow}a_{\downarrow\uparrow}^*r_1r_2^* & a_{\uparrow\downarrow}a_{\downarrow\downarrow}^*r_1 \\ a_{\uparrow\uparrow}^*a_{\downarrow\uparrow}r_1^* & a_{\uparrow\downarrow}^*a_{\downarrow\uparrow}r_1^*r_2 & |a_{\downarrow\uparrow}|^2 & a_{\downarrow\uparrow}a_{\downarrow\downarrow}^*r_2 \\ a_{\uparrow\uparrow}^*a_{\downarrow\downarrow}r_1^*r_2^* & a_{\uparrow\downarrow}^*a_{\downarrow\downarrow}r_1^* & a_{\downarrow\uparrow}^*a_{\downarrow\downarrow}r_2^* & |a_{\downarrow\downarrow}|^2 \end{pmatrix}, \quad (37)$$

where the decoherence factors $r_1(t)$ and $r_2(t)$ are given by

$$r_n(t) = \prod_{k=1}^{N_n} (|\alpha_{nk}|^2 e^{-i2\omega_{nk}t} + |\beta_{nk}|^2 e^{i2\omega_{nk}t}). \quad (38)$$

In general both expansion coefficients α_{nk} , β_{nk} and interaction strengths ω_{nk} are random. For our purposes, we will assume that the baths are identical, which means we let expansion coefficients and interaction strengths of the two baths be equal to each other as $\alpha_{1k} = \alpha_{2k} = \alpha_k$, $\beta_{1k} = \beta_{2k} = \beta_k$ and $\omega_{1k} = \omega_{2k} = \omega_k$. This assumption implies that the decoherence factors of two baths are equal so that $r_1(t) = r_2(t) = r(t)$. Thus, the reduced density matrix of two central spins is simplified to

$$\rho_c = \begin{pmatrix} |a_{\uparrow\uparrow}|^2 & a_{\uparrow\uparrow}a_{\uparrow\downarrow}^*r & a_{\uparrow\uparrow}a_{\downarrow\uparrow}^*r & a_{\uparrow\uparrow}a_{\downarrow\downarrow}^*r^2 \\ a_{\uparrow\uparrow}^*a_{\uparrow\downarrow}r^* & |a_{\uparrow\downarrow}|^2 & a_{\uparrow\downarrow}a_{\downarrow\uparrow}^*|r|^2 & a_{\uparrow\downarrow}a_{\downarrow\downarrow}^*r \\ a_{\uparrow\uparrow}^*a_{\downarrow\uparrow}r^* & a_{\uparrow\downarrow}^*a_{\downarrow\uparrow}|r|^2 & |a_{\downarrow\uparrow}|^2 & a_{\downarrow\uparrow}a_{\downarrow\downarrow}^*r \\ a_{\uparrow\uparrow}^*a_{\downarrow\downarrow}(r^*)^2 & a_{\uparrow\downarrow}^*a_{\downarrow\downarrow}r^* & a_{\downarrow\uparrow}^*a_{\downarrow\downarrow}r^* & |a_{\downarrow\downarrow}|^2 \end{pmatrix}, \quad (39)$$

where

$$r(t) = \prod_{k=1}^N (|\alpha_k|^2 e^{-i2\omega_k t} + |\beta_k|^2 e^{i2\omega_k t}). \quad (40)$$

We immediately observe that the form of ρ_c under the assumption of identical baths is very similar to the form of the output density matrix we obtained for classical noise Hamiltonian. In particular, when the initial expansion coefficients α_k and β_k are equal to each other, we will have exactly the same form of the mapping obtained in Sec. II. Hence, decay of $r(t)$ to zero at later times and the form of the possible Kraus operators in this case guarantee that the qubit exchange symmetry properties of symmetric Bell states $|B_1\rangle$, $|B_2\rangle$ and $|B_3\rangle$ interacting with two local large spin environments will be the same as their behavior under local stochastic noise fields. Since we interpret decay of $r(t)$ as a signature of decoherence, we identify decoherence as the main source of spontaneous breaking of qubit exchange symmetry.

VI. CONCLUSION

We examined the time evolution of exchange-symmetric Bell states for local noise Hamiltonians having the same symmetry. For both classical and quantum noise, we found a rather unexpected result that not all Bell states preserved their symmetry. In fact, we observed that exchange invariance property survived with a maximum probability of 0.5 at the asymptotic limit. We conclude that breaking of exchange symmetry for some possible final states is a characteristic feature of decoherence.

VII. ACKNOWLEDGEMENTS

This work has been partially supported by the Scientific and Technological Research Council of Turkey (TUBITAK) under grant 107T530. The authors would like to thank C. Saçhoğlu and T. Yildirim for helpful discussions, and comments.
